

Practical No. 4

Date:

Aim :

Implementing Lists in python.

Date :

Aim: Implementing lists in python

Theory: List are used to store multiple items in a single variable.

List are created using square brackets.

Create a List:

```
thislist = ["apple", "banana", "cherry"]  
print(thislist)
```

List items

List items are ordered, changeable and allow duplicate values.

List items are indexed, the first item has index [0], the second item has index [1], etc....

Ordered

When it says that lists are ordered, it means that the items have a definite order, & that order will not change. If you add new items to a list, the new items will be placed at the end of the list.

Changeable

The list is changeable, meaning that we can change

add, and remove items in a list after it has been created.

Allow Duplicate Values.

Since lists are indexed, lists can have items with the same value.

code:

```
thislist = ["apple", "banana", "cherry", "apple", "cherry"]
print(thislist)
```

List length:

To determine how many items a list has, use a len() function.

```
thislist = ["apple", "banana", "cherry"]
print(len(thislist))
```

List Items - Data types

List items can be any data types:

```
list_1 = ["apple", "banana", "cherry"]
```

```
list_2 = [1, 5, 7, 9, 3]
```

```
list_3 = [True, False, False, True]
```

A list with strings, integers & boolean values:

```
list_1 = ["abc", 34, True, 40, "bcd", "hex"]
```

Access items:

list items are indexed & you can access them by referring to the index number:

Print the second item of the list:

```
thislist = ["apple", "banana", "cherry"]
```

```
print(thislist[1])
```

Output → ['banana']

Range of Indexes

You can specify a range of indexes by specifying where to start and end the range. When specifying a range, the return value will be a new list with the specified items.

Return the 3rd, 4th & 5th item:

```
thelist = ["apple", "banana", "cherry", "orange", "kiwi",  
           "melon", "mango"]
```

```
print(thelist[2:5])
```

Output → ['cherry', 'orange', 'kiwi']

Check if item exists:

To determine if a specified item is present in a list use the "in" keyword.

```
thisapple = ["apple", "banana", "cherry"]
```

```
if "cherry" in thisapple:
```

```
    print("Yes, it is in fruits")
```

Output → Yes, it is in fruits.

Change item Value :

To change the value of a specific item, refer to the index number :

Change the second number :

```
thislist = ["apple", "banana", "cherry"]
```

```
thislist[1] = "Peach".
```

```
print(thislist)
```

Output → ['apple', 'Peach', 'cherry']

Append items :

To add an item to the end of the list, use the `append()` method.

```
thislist = ["apple", "banana", "cherry", "orange"]
```

```
thislist.append("Peach")
```

```
print(thislist)
```

Output → ['apple', 'banana', 'cherry', 'orange', 'Peach']

Insert items :

To insert a list items at a specified index, use the `insert()` method.

The `insert()` method inserts an item at the specified index :

Insert an item as the 2nd position :

```
thislist = ["apple", "banana", "cherry"]
```

```
thislist.insert(1, "orange")
```

```
print(thislist)
```

Output → ['apple', 'orange', 'banana', 'cherry']

Remove specified item:

The remove () method removes the specified item:

```
thislist = ["apple", "banana", "cherry"]
```

```
thislist.remove("banana")
```

```
print(thislist)
```

Output : ["apple", "cherry"]

Sort list Alphanumerically :

list objects have a sort() method that will

sort the list alphanumerically, by default :

```
thislist = ["orange", "mango", "kiwi", "pineapple",  
            "banana"]
```

```
thislist.sort()
```

```
print(thislist)
```

Output → ['banana', 'kiwi', 'mango', 'orange', 'pineapple']

Sort the list numerically :

```
thislist = [100, 50, 65, 82, 23]
```

```
thislist.sort()
```

```
print(thislist)
```

Output → [23, 50, 65, 82, 100]

l1 = ["apple", "banana", "cherry"]

l2 = ["apple", "banana", "cherry"]

l3 = ["apple", "banana", "cherry"]

l4 = ["apple", "banana", "cherry"]

Remove specified item

The remove() method removes the specified item

l1 = ["apple", "banana", "cherry"]

l1.remove("banana")

print(l1)

Output: ["apple", "cherry"]

Sort list Alphabetically

list objects have a sort() method that will

sort the list alphabetically by default

l1 = ["apple", "banana", "cherry"]

l1.sort()

print(l1)

Output: ["apple", "banana", "cherry"]

l1 = ["apple", "banana", "cherry"]

Sort the list numerically

l1 = [100, 20, 30, 40, 50]

Result: So, we studied the implementation of the lists & operators on lists using python.

Copy a list :

You cannot copy a list simply by typing `list2 = list1`, because : list 2 will be only a ref. to list 1, & changes made in list 1 will automatically also be made in list 2.

Make a copy of a list with the `copy()` method :

```
thismethodlist = ["apple", "banana", "cherry"]
```

```
mylist = thismethodlist.copy()
```

```
print(mylist)
```

Output → ['apple', 'banana', 'cherry']

Join two lists :

There are several ways to join or concatenate, two or more lists in python. One of the easiest ways are by using the "+" operator

```
list1 = ["a", "b", "c"]
```

```
list2 = [1, 2, 3]
```

```
list3 = list1 + list2
```

```
print(list3)
```

Output → ['a', 'b', 'c', 1, 2, 3]

Result : So, we studied the implementation of lists & operations on lists using python.
